Power BI: Project

Dataset

shopify.xlsx

Shopify App Analysis

You have been hired to review the landscape of apps on the Shopify platform, using data scraped from publicly available Shopify websites. You want to figure out what key factors play into the success of a Shopify app.

For each numbered part in this project, you should produce a page in a Power BI report. Each question itself should be a visualization. For each subquestion, take a screenshot of your entire screen to show your work.

The Data

The **shopify.xlsx** dataset contains public data scraped from the **Shopify App Store**. It includes 4 tables:

- **apps:** Details of the apps on Shopify apps marketplace
- **apps_categories:** Join tables to connect apps with categories
- **categories:** Categories of the apps. Each app has multiple categories
- **reviews**: Each review (row) contains information on user opinion about the related app (rating and comment). Also, it contains the response from the developer if

present.

Part 1: App Landscape

First, we'll find key statistics on the types of apps that are out there. This question uses the **Apps** table. Make a new sheet in your Power BI (`.pbix`) file called **App Landscape** for this question. Remember to take a screenshot for each question answered.

1. Make a **KPI Card** (a visual with a single number) that counts the unique number of apps. Add it to your App Landscape sheet.
2. Make a **Line Chart** getting the sum of the review count on the Y-axis, and the lastmod date on the X-Axis. **Hint:** lastmod date should not be in "date hierarchy" format for your X-Axis.
3. Make a **Scatterplot** with the reviews_count on the X axis and the average rating on the Y axis. Annotate your interpretation of this with an inserted **Text Box** next to this scatterplot.

Part 2: Reviews

Make a new sheet in your `.pbix` file for this new section, named **Reviews.** Remember to take a screenshot for each question answered.

1. Create a new Column in the **Reviews** table named `helpful_reviews` using a DAX expression, which multiplies the `rating` by `1+helpful_count` to weigh the reviews by how helpful they've been found. The formula in mathematical form would be `rating * (1+helpful_count)` . Make a Card with the average value of the new `helpful_reviews` column.
2. Create a new Column in the **Reviews** table named `developer_answered` using a DAX expression, which is 1 (or TRUE) if the `developer_reply` column is not blank and 0 (or FALSE) if the column row is blank. Make a scatterplot comparing the average `rating` on the Y-Axis by the value of the `developer_answered` column on the X-Axis.

Part 3: App Reviews

Make a new sheet in your `.pbix` file for this new section, named **App Reviews.** Remember to take a screenshot for each question answered.

1. In the data model, create a new relationship between the **Reviews** table and the **Apps** table. Use the `app_id` column from the **Reviews** table, the `id` column from the **Apps** table. Make the relationship **many-to-one** built as **many** (Reviews table) to **one** (Apps table). Using this new table, make a bar chart with the `developer` on the X-Axis, and the `sum of rating` on the Y-Axis.
2. The chart in the previous question is misleading because an app could have a high `sum of rating` because it has many one-star reviews. Make a new bar chart with `developer` on the X-Axis against the `helpful_review` average on the Y-Axis.
3. Which developers are the most responsive? Make a bar chart with the `developer` from the apps table and the `developer_answered` column you created in question 2.2. Add a **Filter** for this visual only which selects only the rows where `reviews_count` is greater than 500.

Part 4: Submitting your project

As `.pbix` files are too large to share, we will ask you to share 8 screenshots. One screenshot for each sub-question on each page. Remember to organize your `.pbix` project so that it contains one page for each section.

How was the project?
